# INTRODUCTION

## Regression Definition:

- A regression is a statistical analysis assessing the association between two variables. It is used to find the relationship between two variables.
- **Regression Formula:** (another formula produces the same result)

$$\text{Regression Equation}(y) = a + bx$$

$$\text{Slope}(b) = (N\Sigma XY - (\Sigma X)(\Sigma Y)) / (N\Sigma X^2 - (\Sigma X)^2)$$

$$\text{Intercept}(a) = (\Sigma Y - b(\Sigma X)) / N$$

Where:

x and y are the variables.

b = The slope of the regression line

a = The intercept point of the regression line and the y axis.

N = Number of values or elements

X = First Score

Y = Second Score

$\Sigma XY$  = Sum of the product of first and Second Scores

$\Sigma X$  = Sum of First Scores

$\Sigma Y$  = Sum of Second Scores

$\Sigma X^2$  = Sum of square First Scores

# DESIGN

## Linear Regression using Least Square Method

- This formula is called The Normal Equation which is based on Linear Regression using Least Square Method.
- To find the Simple/Linear Regression of given data X and Y
- First find slope, intercept and use it to form regression equation.
  1. Step 1:  
Count the number of values.  $N = 10$
  2. Step 2:  
Find  $X * Y$ ,  $X^2$

X Value	Y Value	X*Y	X*X
1	1.8	$1*1.8=1.8$	$1*1=1$
2	2.4	$2*2.4=4.8$	$2*2=4$
3.3	2.3	$3.3*2.3=7.59$	$3.3*3.3=10.89$
4.3	3.8	$4.3*3.8=16.34$	$4.3*4.3=18.49$
5.3	5.3	$5.3*5.3=28.09$	$5.3*5.3=28.09$
1.4	1.5	$1.4*1.5=2.1$	$1.4*1.4=1.96$
2.5	2.2	$2.5*2.2=5.5$	$2.5*2.5=6.25$
2.8	3.8	$2.8*3.8=10.64$	$2.8*2.8=7.84$
4.1	4.0	$4.1*4.0=16.4$	$4.1*4.1=16.81$
5.1	5.4	$5.1*5.4=27.54$	$5.1*5.1=26.01$

# Linear Regression using Least Square Method

## 3 Step 3:

Find  $\Sigma X$ ,  $\Sigma Y$ ,  $\Sigma XY$ ,  $\Sigma X^2$ .

- $\Sigma X = 31.8$
- $\Sigma Y = 32.5$
- $\Sigma XY = 120.8$
- $\Sigma X^2 = 121.34$

## Step 4:

Substitute in the above slope formula given.

$$\begin{aligned}\text{Slope (b)} &= (N\Sigma XY - (\Sigma X)(\Sigma Y)) / (N\Sigma X^2 - (\Sigma X)^2) \\ &= ((10) * (120.8) - (31.8) * (32.5)) / ((10) * (121.34) - (31.8)^2) \\ &= (1208 - 1033.5) / (1213.4 - 1011.24) \\ &= 174.5 / 202.16 \\ &= 0.86\end{aligned}$$

# Linear Regression using Least Square Method

Step 5:

Now, again substitute in the above intercept formula given.

$$\text{Intercept (a)} = (\Sigma Y - b(\Sigma X)) / N$$

$$= (32.5 - 0.86(31.8)) / 10$$

$$= (32.5 - 27.34) / 10$$

$$= 5.152 / 10$$

$$= 0.5152$$

Step 6:

Then substitute Intercept(a) and Slope(b) in regression equation formula

Linear Regression Equation(y) = a + bx

$$= 0.51 + 0.86x.$$

## Linear Regression using Least Square Method

Step 7:

Suppose if we want to know the approximate y value for the variable  $x = 64$ . Then we can substitute the value in the above equation.

$$\text{Regression Equation}(y) = a + bx$$

$$= -8.098 + 0.19(64).$$

$$= -8.098 + 12.16$$

$$= 4.06$$

## Non-linear Regression:

Regression Equation  $y = a + b^2$

We can still use Linear Regression formula

$$\text{Slope}(b) = (N\Sigma \underline{P}Y - (\Sigma \underline{P})(\Sigma Y)) / (N\Sigma \underline{P}^2 - (\Sigma \underline{P})^2)$$

$$\text{Intercept}(a) = (\Sigma Y - b(\Sigma \underline{P})) / N$$

Where  $\underline{P} = X * X$

## Non-linear Regression:

To find the Simple Non-Linear Regression of given data X and Y  
We can simply create  $\underline{X}$  from X

To find regression equation, we will first find slope, intercept and use it to form regression equation.

- Step 1:

Count the number of values.  $N = 10$

- Step 2:

Find  $\underline{X} * Y$ ,  $\underline{X}^2$

X Value	Y Value	$\underline{X}=X*X$
1	1.8	$1*1=1$
2	2.4	$2*2=4$
3.3	2.3	$3.3*3.3=10.89$
4.3	3.8	$4.3*4.3=18.49$
5.3	5.3	$5.3*5.3=28.09$
1.4	1.5	$1.4*1.4=1.96$
2.5	2.2	$2.5*2.5=6.25$
2.8	3.8	$2.8*2.8=7.84$
4.1	4.0	$4.1*4.1=16.81$
5.1	5.4	$5.1*5.1=26.01$

## Non-linear Regression:

Step 3:

Find  $\Sigma X$ ,  $\Sigma Y$ ,  $\Sigma XY$ ,  $\Sigma X^2$ .

$$\Sigma X = 121.34$$

$$\Sigma Y = 32.5$$

$$\Sigma XY = 509.5$$

$$\Sigma X^2 = 2329.92$$

Step 4:

Substitute in the above slope formula given.

<u>X</u> Value	Y Value	<u>X</u> *Y	<u>X</u> * <u>X</u>
1	1.8	1*1.8=1.8	1*1=1
4	2.4	4*2.4=9.6	4*4=16
10.89	2.3	10.89*2.3=25.04	10.89*10.89=118.59
18.49	3.8	18.49*3.8=70.02	18.49*18.49=341.88
28.09	5.3	28.09*5.3=148.87	28.09*28.09=789
1.96	1.5	1.96*1.5=2.94	1.96*1.96=3.84
6.25	2.2	6.25*2.2=13.75	6.25*6.25=39.06
7.84	3.8	7.84*3.8=29.79	7.84*7.84=61.46
16.81	4.0	16.81*4.0=67.24	16.81*16.81=282.57
26.01	5.4	26.01*5.4=140.45	26.01*26.01=676.52

$$\begin{aligned}\text{Slope (b)} &= (N\Sigma XY - (\Sigma X)(\Sigma Y)) / (N\Sigma X^2 - (\Sigma X)^2) \\&= ((10) * (509.5) - (121.34) * (32.5)) / ((10) * (2329.92) - (121.34^2)) \\&= (5095 - 3943.55) / (23299.2 - 14723.39) \\&= 1151.45 / 8575.80 \\&= 0.1346\end{aligned}$$

- Step 5:

Now, again substitute in the above intercept formula given.

$$\begin{aligned}\text{Intercept (a)} &= (\Sigma Y - b(\Sigma X)) / N \\ &= (32.5 - 0.00021(121.34)) / 10 \\ &= (32.5 - 0.0254) / 10 \\ &= 32.474 / 10 \\ &= 1.6168\end{aligned}$$

Step 6:

Then substitute these values in regression equation formula

$$\begin{aligned}\text{Regression Equation}(y) &= \underline{a} + \underline{b}x^2 \\ &= 1.6168 + 0.1346x^2\end{aligned}$$

Step 7:

Suppose if we want to know the approximate y value for the variable  $x = 64$ . Then we can substitute the value in the above equation.

$$\text{Regression Equation}(y) = a + bx^2$$

$$\begin{aligned}&= 1.6168 + 0.1346 (64 * 64) \\ &= 1.6168 + 551.32 \\ &= 552.93\end{aligned}$$

# Mean Square Error:

## Mean Squared Error (MSE)

- The **Mean Squared Error (MSE)** is a measure of how close a fitted line is to data points.
  - The **smaller** the **MSE**, the **closer** the **fit** is to the **data**.
- If  $\hat{Y}$  is a **vector** of **n predictions**, and  $Y$  is the **vector** of the **true values**, then the (estimated) **MSE** of the **predictor** is:

$$\text{MSE} = \frac{1}{n} \sum_{i=1}^n (\hat{Y}_i - Y_i)^2.$$

Training Set						Validation Set					
Real Data		Model 1		Model 2		Real Data		Model 1		Model 2	
x	y	x	$\hat{y}$	x	$\hat{y}$	x	y	x	$\hat{y}$	x	$\hat{y}$
1	1.8	1	1.38	1	1.75	1	1.7	1	1.81	1	1.91
2	2.4	2	2.24	2	2.15	2	2.7	2	3.014	2	2.74
3.3	2.3	3.3	3.358	3.3	3.08	3.3	2.5	3.3	3.702	3.3	3.45

5.3	5.3	5.3	5.078	5.3	5.39	5.3	5.5	5.3	4.902	5.3	5.11

## Training Set

- Model 1

- MSE

$$= [(1.38-1.8)^2 + (2.24-2.4)^2 + (3.358-2.3)^2 + (4.218-3.8)^2 + (5.078-5.3)^2 + (1.74-1.5)^2 + (2.67-2.2)^2 + (2.92-3.8)^2 + (4.04-4.0)^2 + (4.90-5.4)^2]/10$$

$$= 0.28$$

- Model 2

- MSE

$$[(1.75-1.8)^2 + (2.15-2.4)^2 + (3.08-2.3)^2 + (4.10-3.8)^2 + (5.39-5.3)^2 + (1.88-1.5)^2 + (2.45-2.2)^2 + (2.67-3.8)^2 + (3.87-4.0)^2 + (5.11-5.4)^2]/10$$

$$= 0.24$$

## Validation Set

---

- **Model 1**

- MSE

$$= [(1.81 - \underline{1.7})^2 + (3.014 - 2.7)^2 + (3.70 - 2.5)^2 + (4.56 - 2.8)^2 + (4.90 - 5.5)^2] / 5$$

$$= 1.0035$$

- **Model 2**

- MSE

$$= [(1.91 - \underline{1.7})^2 + (2.74 - 2.7)^2 + (3.45 - 2.5)^2 + (4.59 - 2.8)^2 + (5.11 - 5.5)^2] / 5$$

$$= 0.86$$

```
max(Training_Set_MSE, Validation_Set_MSE) / min(Training_Set_MSE,  
Validation_Set_MSE)
```

- Compare Model 1 and Model 2
  - Model 1

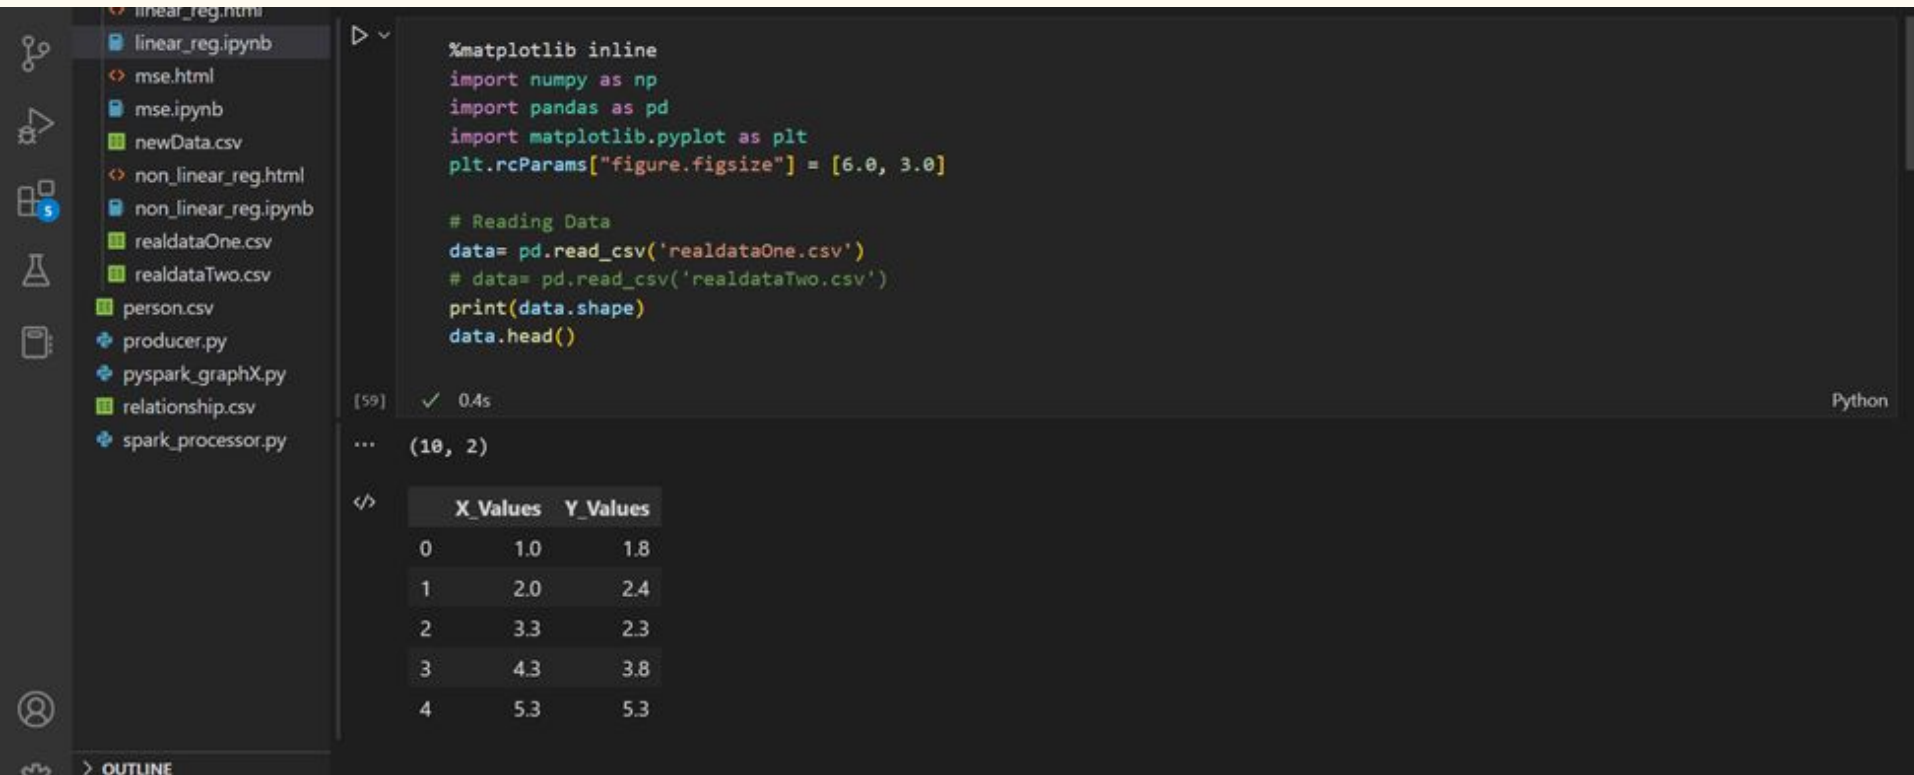

$$1.003 / 0.297 = 3.38$$

- Model 2

$$0.860 / 0.247 = 3.48$$

- **Conclusion**
  - **Model 1 is a better model**

# IMPLEMENTATION: Linear Regression

The screenshot displays a Jupyter Notebook environment. On the left, a file explorer shows a project structure with files like `linear_reg.ipynb`, `mse.html`, `mse.ipynb`, `newData.csv`, `non_linear_reg.html`, `non_linear_reg.ipynb`, `realdataOne.csv`, `realdataTwo.csv`, `person.csv`, `producer.py`, `pyspark_graphX.py`, `relationship.csv`, and `spark_processor.py`.

The central code editor contains the following Python code:

```
%matplotlib inline
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
plt.rcParams["figure.figsize"] = [6.0, 3.0]

# Reading Data
data= pd.read_csv('realdataOne.csv')
# data= pd.read_csv('realdataTwo.csv')
print(data.shape)
data.head()
```

The output area shows the execution of the code, resulting in the shape of the data and a preview of its first rows:

# Linear Graph

## Validation phase:

The screenshot shows a Jupyter Notebook interface. On the left is a file explorer with icons for a folder and a file. The file list includes: realdataOne.csv, realdataTwo.csv, person.csv, producer.py, pyspark\_graphX.py, relationship.csv, and spark\_processor.py. The main area displays a code cell with the following Python code:

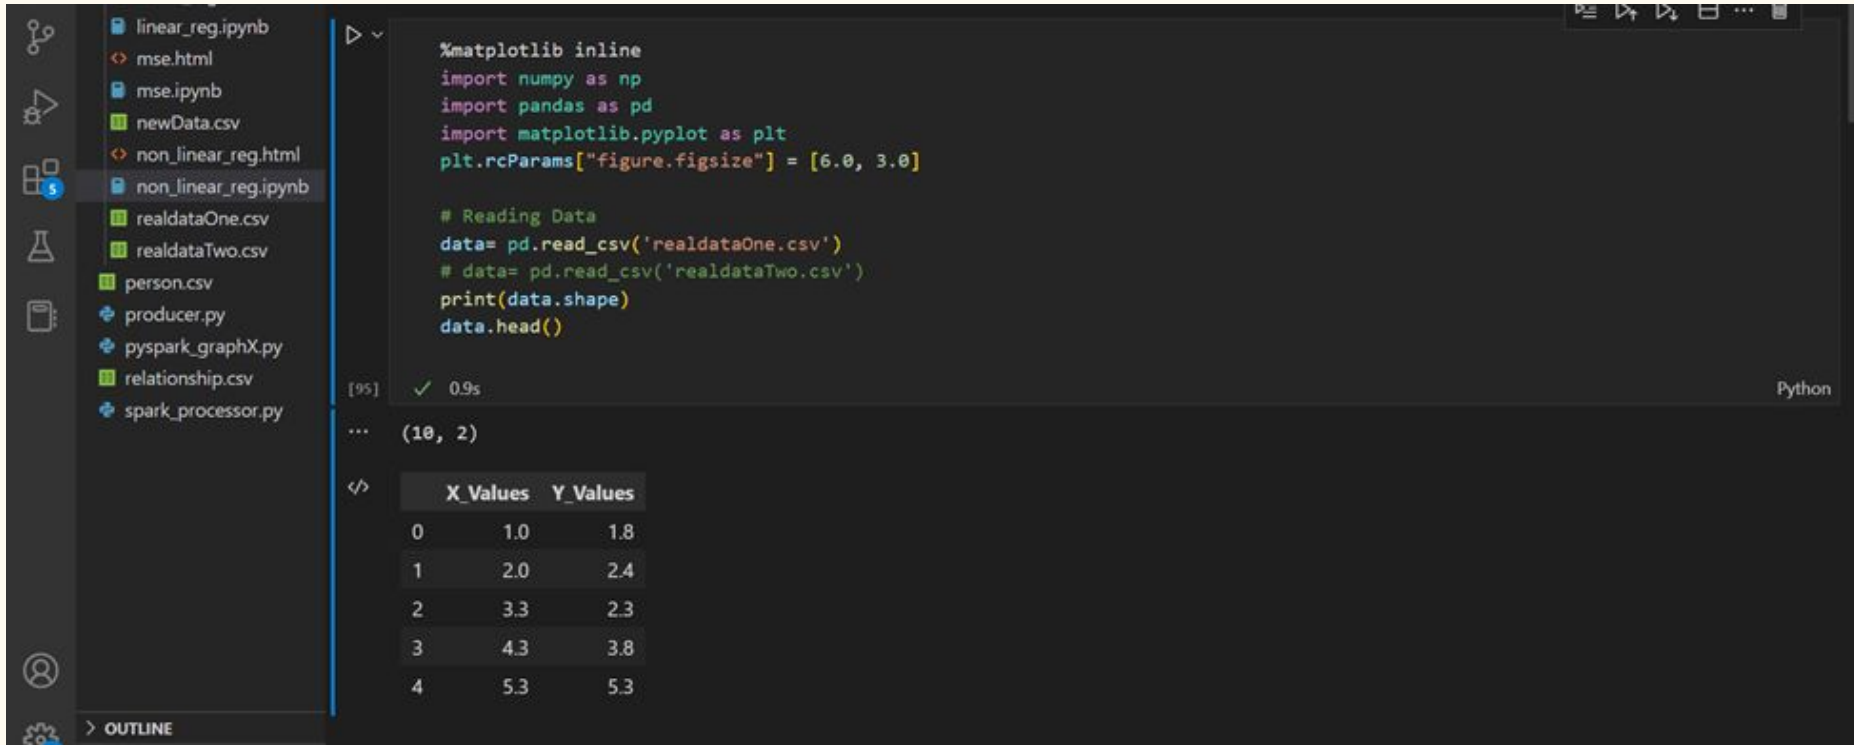

```
# validation phase
# After calculating a1, b1, a2, b2 in Training Phase, the values are not changed with the new Real Data Sets in Validation Ph.
# Only  $\hat{y}$  values are changed with the new Real Data Sets.
# Regression Equation( $y$ ) =  $a + bx$ 
x = np.array([1.5, 2.9, 3.7, 4.7, 5.1])
y = a + b * x
print(y)
```

Below the code, the execution status is shown as [28] ✓ 0.3s. The output of the code is displayed as:

```
... [1.81  3.014 3.702 4.562 4.906]
```

The word "Python" is visible in the bottom right corner of the code cell area.

# IMPLEMENTATION: NonLinear Regression

The screenshot shows a Jupyter Notebook environment. The left sidebar contains a file explorer with the following files: linear\_reg.ipynb, mse.html, mse.ipynb, newData.csv, non\_linear\_reg.html, non\_linear\_reg.ipynb (selected), realdataOne.csv, realdataTwo.csv, person.csv, producer.py, pyspark\_graphX.py, relationship.csv, and spark\_processor.py. The main area displays a Python script with the following code:

```
%matplotlib inline
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
plt.rcParams["figure.figsize"] = [6.0, 3.0]

# Reading Data
data= pd.read_csv('realdataOne.csv')
# data= pd.read_csv('realdataTwo.csv')
print(data.shape)
data.head()
```

The output of the script is shown below the code cell:

```
[95] ✓ 0.9s
... (10, 2)
```

The output is a table with 10 rows and 2 columns, labeled X\_Values and Y\_Values:

	X_Values	Y_Values
0	1.0	1.8
1	2.0	2.4
2	3.3	2.3
3	4.3	3.8
4	5.3	5.3

The bottom of the interface shows a tab labeled "OUTLINE".

Validation_Set_MSE = 0.86088000000000001
ModelTwo = Validation_Set_MSE / Training_Set_MSE
print("Model 2 MSE :", round(ModelTwo,2))

# Compare to find better model
if ( ModelTwo < ModelOne ):
    print("Model 2 is a better model")
else:
    print("Model 1 is a better model")
```

The output of the code cell is:

```
[23] ✓ 0.3s
... Model 1 MSE : 3.38
Model 2 MSE : 3.48
Model 1 is a better model
```

# Test Phase:

The screenshot shows a Jupyter Notebook environment with a file explorer on the left and a code editor on the right. The file explorer lists several files: linear\_reg.ipynb, mse.html, mse.ipynb, newData.csv, non\_linear\_reg.html, non\_linear\_reg.ipynb, realdataOne.csv, realdataTwo.csv, person.csv, producer.py, pyspark\_graphX.py, relationship.csv, and spark\_processor.py. The code editor displays a Python script for the test phase of a linear regression model. The script includes comments explaining the process of finding the values of y based on the MSE, choosing the linear regression equation, and calculating the slope and intercept. The code defines an array x, sets the intercept a and slope b, and calculates the predicted values y using the equation y = a + b \* x. The output of the code is displayed below the code cell, showing the predicted values for the input data.

```
***** Test phase *****

# After getting better model based on MSE, we then find the values of y
# In our case MODEL 1 is better so we choose linear Regression Equation(y):
#  $\hat{y} = a_1 + b_1 * x$ 
# we will take the value of slope(b) and intercept(a) same what we calculated before from our first data set
# slope(b) is: 0.86
# intercept(a): 0.52
x = np.array([1.4, 2.5, 3.6, 4.5, 5.4])
a = 0.52
b = 0.86
y = a + b * x
print(y)
```

Training Phase			Validation Phase			Test Phase	
Real Data Set 1 50% of the collected data	<u>Model 1: Linear Regression</u>	<u>Model 2: Non-Linear Regression</u>	Real Data Set 2 25% of the collected data	<u>Model 1: Linear Regression</u>	<u>Model 2: Non-Linear Regression</u>	Real Data Set 3 25% of the collected data	The better model ( <u>Model 1</u> or <u>Model 2</u> ) selected from the <b>Validation Phase</b> based on the analysis of <u>overfitting</u> will be used to calculate $\hat{y}$

- After calculating **a1, b1, a2, b2** in **Training Phase**, the values are not changed with the new **Real Data Sets** in **Validation Phase** and **Test Phase**.
- Only  $\hat{y}$  values are changed with the new **Real Data Sets**.

x	y	$\hat{y}=a1 + b1 * x$	$\hat{y}=a2 + b2 * x^2$	x	y	$\hat{y}=a1 + b1 * x$	$\hat{y}=a2 + b2 * x^2$	x	$\hat{y}=a1 + b1 * x$ or $\hat{y}=a2 + b2 * x^2$
1	1.8	1.38	1.75	1.5	1.7	1.81	1.91	1.4	1.724
2	2.4	2.24	2.15	2.9	2.7	3.014	2.74	2.5	2.67
3.3	2.3	3.358	3.08	3.7	2.5	3.702	3.45	3.6	3.616
4.3	3.8	4.218	4.10	4.7	2.8	4.562	4.59	4.5	4.39
5.3	5.3	5.078	5.39	5.1	5.5	4.902	5.11	5.4	5.164
1.4	1.5	1.724	1.88	X	X	X	X	X	X
2.5	2.2	2.67	2.45	X	X	X	X	X	X
2.8	3.8	2.928	2.67	X	X	X	X	X	X
4.1	4.0	4.046	3.87	X	X	X	X	X	X
5.1	5.4	4.906	5.11	X	X	X	X	X	X

# Enhancement Ideas:

- This **data set** is used to minimize **overfitting**.
  - To verify that any **increase** in **accuracy** over the **training data set** actually yields an **increase** in **accuracy** over a **data set** that has not been shown to the **model** before, or at least the **model** hasn't **trained** on it (i.e. validation data set).
    - If the **accuracy** over the **training data set** **increases**, but the **accuracy** over then **validation data set** stays the **same** or **decreases**, then you're **overfitting** your **model** and you should **stop training**.
  - A **test set** (i.e., **validation set**) is a set of **data** that is **independent** of the **training data**, but that follows the same **probability distribution** as the **training data**.
    - If a **model** fit to the **training set** also fits the **test set** well, **minimal overfitting** has **taken place**.
    - If the **model** fits the **training set** **much better** than it fits the **test set**, **overfitting** is likely the **cause**.
- In order to avoid **overfitting**, when any **classification parameter** needs to be adjusted, it is necessary to have a **validation set** in addition to the **training** and **test sets**.
  - For example if the most suitable classifier for the problem is sought,
    - **Training Data** is used to train the **candidate algorithms**.
    - **Validation Data** is used to **compare** their **performances** and decide **which one to take**.
    - **Test Data** is used to obtain the **performance characteristics** such as **accuracy**, **sensitivity**, **specificity**.

# Conclusion:

- If the **accuracy** over the **training data set increases**, but the **accuracy** over the **validation data set** stays the **same** or **decreases**, then you're **overfitting your model** and you should **stop training**.
- If the model fits the **training set** much better than it fits the **test set** (i.e., **validation set**), **overfitting** is likely the cause.
